Digital Filters

Questions

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).
- The input to the filter is a sequence of samples, and the output from the filter is also a sequence of samples.

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).
- The input to the filter is a sequence of samples, and the output from the filter is also a sequence of samples.
- So anything that is done to a sequence of data is a “Digital Filter”.

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).
- The input to the filter is a sequence of samples, and the output from the filter is also a sequence of samples.
- So anything that is done to a sequence of data is a “Digital Filter”.
- The filter can be realised using shift registers or assembly code or C code,

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).
- The input to the filter is a sequence of samples, and the output from the filter is also a sequence of samples.
- So anything that is done to a sequence of data is a “Digital Filter”.
- The filter can be realised using shift registers or assembly code or C code,

- A Digital Filter is an algorithm or process that converts one digital sequence (called the input $x(n)$) to another (called the output $y(n)$).
- The input to the filter is a sequence of samples, and the output from the filter is also a sequence of samples.
- So anything that is done to a sequence of data is a “Digital Filter”.
- The filter can be realised using shift registers or assembly code or C code,

- The most commonly used filters are Linear Filter. These have a linear relationship (straight line through the origin) between input and output **sequences**.

Digital filters offer many gains over analogue filters, some are listed below.

1. Very difficult to realise analogue filters with low cut-off frequencies.
2. Easy to change characteristics of filter.
3. No ageing/degradation or temperature dependencies.
4. Can be VERY sophisticated, and not too expensive.

[Questions](#)

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);
- we obtain a sequence $\{-1 \ -1 \ 2 \ -1\}$. This new sequence is obtained by doing $\{1-2 \ 2-3 \ 3-1 \ 1-2\}$.

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);
- we obtain a sequence $\{-1 \ -1 \ 2 \ -1\}$. This new sequence is obtained by doing $\{1-2 \ 2-3 \ 3-1 \ 1-2\}$.

This is Digital Filtering.

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);
- we obtain a sequence $\{-1 \ -1 \ 2 \ -1\}$. This new sequence is obtained by doing $\{1-2 \ 2-3 \ 3-1 \ 1-2\}$.

This is Digital Filtering. The filter is described using the following notation : the current number is x_n , and the previous one is x_{n-1} .

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);
- we obtain a sequence $\{-1 \ -1 \ 2 \ -1\}$. This new sequence is obtained by doing $\{1-2 \ 2-3 \ 3-1 \ 1-2\}$.

This is Digital Filtering. The filter is described using the following notation : the current number is x_n , and the previous one is x_{n-1} . If a number x_{n-1} is subtracted from an adjacent number x_n ;

Example 1

- Consider the sequence of numbers $\{1 \ 2 \ 3 \ 1 \ 2\}$,
- if we specify a digital filter as subtracting adjacent samples from each other (in this case we subtract the number on the right from the number on the left);
- we obtain a sequence $\{-1 \ -1 \ 2 \ -1\}$. This new sequence is obtained by doing $\{1-2 \ 2-3 \ 3-1 \ 1-2\}$.

This is Digital Filtering. The filter is described using the following notation : the current number is x_n , and the previous one is x_{n-1} . If a number x_{n-1} is subtracted from an adjacent number x_n ; mathematically the output y_n can be written as

$$y_n = x_n - x_{n-1}$$

Example 1

- This addition, subtraction and scaling of adjacent numbers in a sampled sequences results in scaling of the frequency spectrum.

Questions

- The $\mathbb{Z}$ Transform of a sequence $x(n)$ is defined as

$$\mathbb{Z}\{x(n)\} = \sum_{n=0}^{\infty} x(n) Z^{-n}$$

where Z is a complex number.

[Questions](#)

- The $\mathbb{Z}$ Transform of a sequence $x(n)$ is defined as

$$\mathbb{Z}\{x(n)\} = \sum_{n=0}^{\infty} x(n)Z^{-n}$$

where Z is a complex number.

- The transformation is simply done by replacing x_{n-i} with $X \cdot Z^{-i}$ where i is any integer and X is the representation of x in the $\mathbb{Z}$ Domain.
Remember $Z^0 = 1$.

Digital Filters

A Digital Impulse is a sequence that contains a single unity element followed by zeros. The impulse response is the response of a filter (the output from the filter) if the input was an impulse.

A Digital Impulse is a sequence that contains a single unity element followed by zeros. The impulse response is the response of a filter (the output from the filter) if the input was an impulse.

- If the impulse response of a filter results in an output that has a finite number of non-zero outputs the filter is called a Finite Impulse Response (FIR) filter.

A Digital Impulse is a sequence that contains a single unity element followed by zeros. The impulse response is the response of a filter (the output from the filter) if the input was an impulse.

- If the impulse response of a filter results in an output that has a finite number of non-zero outputs the filter is called a Finite Impulse Response (FIR) filter. Thus if the sequence y_n in the figure above is a finite length sequence; the filter is a FIR filter

A Digital Impulse is a sequence that contains a single unity element followed by zeros. The impulse response is the response of a filter (the output from the filter) if the input was an impulse.

- If the impulse response of a filter results in an output that has a finite number of non-zero outputs the filter is called a Finite Impulse Response (FIR) filter. Thus if the sequence y_n in the figure above is a finite length sequence; the filter is a FIR filter
- Filters that create an infinite number of non-zero outputs and are called Infinite Impulse Response Filters (IIR Filters).

A filter is stable if its impulse response decays to zero as time (or the number of samples) increases.

The $\mathbb{Z}$ Domain relationship between input and output sequences is the transfer function of the filter.

The $\mathbb{Z}$ Domain relationship between input and output sequences is the transfer function of the filter.

- This results in a complex number describing the relationship between input and output.

The $\mathbb{Z}$ Domain relationship between input and output sequences is the transfer function of the filter.

- This results in a complex number describing the relationship between input and output.
- This complex number is also best viewed as having magnitude and phase.

The $\mathbb{Z}$ Domain relationship between input and output sequences is the transfer function of the filter.

- This results in a complex number describing the relationship between input and output.
- This complex number is also best viewed as having magnitude and phase.
- The unit circle in the $\mathbb{Z}$ Domain is the complex number $1e^{j\theta}$

The $\mathbb{Z}$ Domain relationship between input and output sequences is the transfer function of the filter.

- This results in a complex number describing the relationship between input and output.
- This complex number is also best viewed as having magnitude and phase.
- The unit circle in the $\mathbb{Z}$ Domain is the complex number $1e^{j\theta}$
- θ on the unit circle is the Fourier Transform and is equal to $2\pi \frac{f}{F_s}$, where f is the frequency and F_s is the sampling frequency.

$$Z = e^{j2\pi \frac{f}{F_s}} = e^{j\theta}$$

Also $-\pi \leq \theta \leq \pi$ or $0 \leq \theta \leq 2\pi$.

Magnitude Response On Unit Circle

- This describes the relationship between the magnitude of the output to the magnitude of the input.
- Filters can amplify, attenuate or leave unchanged the magnitude of the input depending on the value of Z .

Phase Response On Unit Circle

- The Phase Response represents the phase offset between the input and output from the filter.
- Filters that operate with real numbers must have phase responses that are anti-symmetric about $\theta = 0$. This means for a given sampling frequency F_s , the phase response at a frequency f must be equal to the negative value of the phase response at a frequency $-f$.

Example 4

Suppose a digital filter is specified with the following transfer function

$$\frac{Y}{X} = \frac{(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))(Z - (-1))}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}$$

We can evaluate the manner of combining x_n and y_n as follows

Example 4

Suppose a digital filter is specified with the following transfer function

$$\frac{Y}{X} = \frac{(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))(Z - (-1))}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}$$

We can evaluate the manner of combining x_n and y_n as follows

■ Expanding the transfer function gives

$$\frac{Y}{X} = \frac{(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))(Z - (-1))}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}$$

Example 4

Suppose a digital filter is specified with the following transfer function

$$\frac{Y}{X} = \frac{(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))(Z - (-1))}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}$$

We can evaluate the manner of combining x_n and y_n as follows

■ Expanding the transfer function gives

$$\begin{aligned} \frac{Y}{X} &= \frac{(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))(Z - (-1))}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{[(Z - (0.5 + j0.5))(Z - (0.5 - j0.5))][(Z - (-1))]}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \end{aligned}$$

Example 4

$$\begin{aligned} \frac{Y}{X} = & [Z^2 - (0.5 - j0.5)Z - (0.5 + j0.5)Z + \\ & (0.5 + j0.5)(0.5 - j0.5)] \times \\ & \times \frac{[(Z - (-1))]}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \end{aligned}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= [Z^2 - (0.5 - j0.5)Z - (0.5 + j0.5)Z + \\ &\quad (0.5 + j0.5)(0.5 - j0.5)] \times \\ &\quad \times \frac{[(Z - (-1))]}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= [Z^2 - 0.5Z + j0.5Z - 0.5Z - j0.5Z + 0.5^2 + 0.5^2] \times \\ &\quad \times \frac{(Z + 1)}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}\end{aligned}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= [Z^2 - (0.5 - j0.5)Z - (0.5 + j0.5)Z + \\ &\quad (0.5 + j0.5)(0.5 - j0.5)] \times \\ &\quad \times \frac{[(Z - (-1))]}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= [Z^2 - 0.5Z + j0.5Z - 0.5Z - j0.5Z + 0.5^2 + 0.5^2] \times \\ &\quad \times \frac{(Z + 1)}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{[Z^2 - Z + 0.5][(Z + 1)]}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}\end{aligned}$$

Example 4

$$\frac{Y}{X} = \frac{Z^3 - Z^2 + 0.5Z + Z^2 - Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - Z^2 + 0.5Z + Z^2 - Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))}\end{aligned}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - Z^2 + 0.5Z + Z^2 - Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z^2 + (j0.9)Z - (j0.9)Z + 0.9^2)(Z - (-0.9))}\end{aligned}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - Z^2 + 0.5Z + Z^2 - Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z^2 + (j0.9)Z - (j0.9)Z + 0.9^2)(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z^2 + 0.81)(Z + 0.9)}\end{aligned}$$

Example 4

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - Z^2 + 0.5Z + Z^2 - Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z - (j0.9))(Z - (-j0.9))(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z^2 + (j0.9)Z - (j0.9)Z + 0.9^2)(Z - (-0.9))} \\ &= \frac{Z^3 - 0.5Z + 0.5}{(Z^2 + 0.81)(Z + 0.9)} \\ &= \frac{Z^3 - 0.5Z + 0.5}{Z^3 + 0.9Z^2 + 0.81Z + 0.729}\end{aligned}$$

- Rewriting this using only negative powers of Z ,

$$\frac{Y}{X} = \frac{Z^3 - 0.5Z + 0.5}{Z^3 + 0.9Z^2 + 0.81Z + 0.729}$$

- Rewriting this using only negative powers of Z ,

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - 0.5Z + 0.5}{Z^3 + 0.9Z^2 + 0.81Z + 0.729} \\ &= \frac{(Z^3 - 0.5Z + 0.5)/Z^3}{(Z^3 + 0.9Z^2 + 0.81Z + 0.729)/Z^3}\end{aligned}$$

- Rewriting this using only negative powers of Z ,

$$\begin{aligned}\frac{Y}{X} &= \frac{Z^3 - 0.5Z + 0.5}{Z^3 + 0.9Z^2 + 0.81Z + 0.729} \\ &= \frac{(Z^3 - 0.5Z + 0.5)/Z^3}{(Z^3 + 0.9Z^2 + 0.81Z + 0.729)/Z^3} \\ &= \frac{1 - 0.5Z^{-2} + 0.5Z^{-3}}{1 + 0.9Z^{-1} + 0.81Z^{-2} + 0.729Z^{-3}}\end{aligned}$$

Example 4

$$Y(1 + 0.9Z^{-1} + 0.81Z^{-2} + 0.729Z^{-3}) = \\ X(1 - 0.5Z^{-2} + 0.5Z^{-3})$$

Example 4

$$\begin{aligned} Y(1 + 0.9Z^{-1} + 0.81Z^{-2} + 0.729Z^{-3}) &= \\ X(1 - 0.5Z^{-2} + 0.5Z^{-3}) \\ Y + 0.9YZ^{-1} + 0.81YZ^{-2} + 0.729YZ^{-3} &= \\ X - 0.5XZ^{-2} + 0.5XZ^{-3} \end{aligned}$$

$$\begin{aligned} Y(1 + 0.9Z^{-1} + 0.81Z^{-2} + 0.729Z^{-3}) &= \\ X(1 - 0.5Z^{-2} + 0.5Z^{-3}) \\ Y + 0.9YZ^{-1} + 0.81YZ^{-2} + 0.729YZ^{-3} &= \\ X - 0.5XZ^{-2} + 0.5XZ^{-3} \end{aligned}$$

$$Y = X - 0.5XZ^{-2} + 0.5XZ^{-3} - 0.9YZ^{-1} - 0.81YZ^{-2} - 0.729YZ^{-3}$$

Example 4

$$\begin{aligned} Y(1 + 0.9Z^{-1} + 0.81Z^{-2} + 0.729Z^{-3}) &= \\ X(1 - 0.5Z^{-2} + 0.5Z^{-3}) \\ Y + 0.9YZ^{-1} + 0.81YZ^{-2} + 0.729YZ^{-3} &= \\ X - 0.5XZ^{-2} + 0.5XZ^{-3} \end{aligned}$$

$$Y = X - 0.5XZ^{-2} + 0.5XZ^{-3} - 0.9YZ^{-1} - 0.81YZ^{-2} - 0.729YZ^{-3}$$

$$y_n = x_n - 0.5x_{n-2} + 0.5x_{n-3} - 0.9y_{n-1} - 0.81y_{n-2} - 0.729y_{n-3}$$

Stability in the $\mathbb{Z}$ Domain

- The criteria of stability in the $\mathbb{Z}$ Domain is that ALL observed poles lie WITHIN the unit circle.

Stability in the $\mathbb{Z}$ Domain

- The criteria of stability in the $\mathbb{Z}$ Domain is that ALL observed poles lie WITHIN the unit circle.
- If this criteria is not met, the the implication is that the summation in the definition of the $\mathbb{Z}$ transform will become infinite.

$$\mathbb{Z}\{x(n)\} = \sum_{n=0}^{\infty} x(n)Z^{-n}$$

Stability in the $\mathbb{Z}$ Domain

- The criteria of stability in the $\mathbb{Z}$ Domain is that ALL observed poles lie WITHIN the unit circle.
- If this criteria is not met, the the implication is that the summation in the definition of the $\mathbb{Z}$ transform will become infinite.

$$\mathbb{Z}\{x(n)\} = \sum_{n=0}^{\infty} x(n)Z^{-n}$$

Note the stability of a filter cannot be predicted by looking at the magnitude and phase response of the filter on the unit circle. Only the location of the poles in the entire $\mathbb{Z}$ Domain determine the stability of the filter.

Questions

- FIR Filters are filters with a finite impulse response.
- Assuming the impulse response of a filter is

$$[h_0, h_1, h_2, \dots, h_{k-1}]$$

If the input sampled sequence to the filter is

$$[x_n, x_{n-1}, x_{n-2} \dots]$$

The output sequence is

$$y_n = x_n h_0 + x_{n-1} h_1 + \dots + x_{n-k+1} h_{k-1}$$

The filter can be represented using a delay line as follows

- Remember, the sequence $h_0, h_1 \cdots h_{k-1}$ is just a sequence of k numbers stored in memory.
- The filter uses only the k most recent samples of the input data to compute the output.
 - ◆ Thus only the sequence $x_n, x_{n-1} \cdots, x_{n-(k-1)}$ is used (where x_n is the current sample).
 - ◆ Older samples are discarded.

Questions

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed.

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed. The numbers to the left of the point represent the integer part and the numbers to the right represent the fractional part.

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed. The numbers to the left of the point represent the integer part and the numbers to the right represent the fractional part.

For example in binary

$$1.1101 = 1 \times 2^0 + 1 \times 2^{-1} + 1 \times 2^{-2} + 0 \times 2^{-3} + 1 \times 2^{-4} = 1.8125$$

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed. The numbers to the left of the point represent the integer part and the numbers to the right represent the fractional part.

For example in binary

$$1.1101 = 1 \times 2^0 + 1 \times 2^{-1} + 1 \times 2^{-2} + 0 \times 2^{-3} + 1 \times 2^{-4} = 1.8125$$

If the decimal point is shifted,

$$11.101 = 1 \times 2^1 + 1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3} = 3.625$$

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed. The numbers to the left of the point represent the integer part and the numbers to the right represent the fractional part.

For example in binary

$$1.1101 = 1 \times 2^0 + 1 \times 2^{-1} + 1 \times 2^{-2} + 0 \times 2^{-3} + 1 \times 2^{-4} = 1.8125$$

If the decimal point is shifted,

$$11.101 = 1 \times 2^1 + 1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3} = 3.625$$

Only positive numbers can be represented in this manner.

In a fixed point representation, it is assumed that the position of the decimal/binary point is fixed. The numbers to the left of the point represent the integer part and the numbers to the right represent the fractional part.

For example in binary

$$1.1101 = 1 \times 2^0 + 1 \times 2^{-1} + 1 \times 2^{-2} + 0 \times 2^{-3} + 1 \times 2^{-4} = 1.8125$$

If the decimal point is shifted,

$$11.101 = 1 \times 2^1 + 1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3} = 3.625$$

Only positive numbers can be represented in this manner. The manner in which negative numbers are represented leads to different forms of fixed point arithmetic.

- The most significant bit represents the sign of the number.

- The most significant bit represents the sign of the number.
- Zero usually represents positive numbers and one represents negative numbers.

- The most significant bit represents the sign of the number.
- Zero usually represents positive numbers and one represents negative numbers. The number zero has two representations $10000 \dots$ and $00000 \dots$.

For example

$01.101 =$

- The most significant bit represents the sign of the number.
- Zero usually represents positive numbers and one represents negative numbers. The number zero has two representations $10000 \dots$ and $00000 \dots$.

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

- The most significant bit represents the sign of the number.
- Zero usually represents positive numbers and one represents negative numbers. The number zero has two representations $10000 \dots$ and $00000 \dots$.

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

$$11.101 =$$

- The most significant bit represents the sign of the number.
- Zero usually represents positive numbers and one represents negative numbers. The number zero has two representations $10000 \dots$ and $00000 \dots$.

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

$$11.101 = -1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = -1.625$$

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number.

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number. There are two ways of representing zero (just like the Sign-Magnitude notation).

For example

01.101 =

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number. There are two ways of representing zero (just like the Sign-Magnitude notation).

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number. There are two ways of representing zero (just like the Sign-Magnitude notation).

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

$$10.010 =$$

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number. There are two ways of representing zero (just like the Sign-Magnitude notation).

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

$$10.010 = -1 \times \hat{0}.\hat{0}\hat{1}\hat{0} =$$

1's-Complement

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number. There are two ways of representing zero (just like the Sign-Magnitude notation).

For example

$$01.101 = +1 \times [1 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}] = +1.625$$

$$10.010 = -1 \times \hat{0}\hat{.}\hat{0}\hat{1}\hat{0} = -1 \times 1.101 = -1.625$$

2's-Complement

- Positive numbers are identical as the Sign-Magnitude form.

- Positive numbers are identical as the Sign-Magnitude form.
- Negative numbers are obtained by complementing all the bits of the positive number and **adding** a 1 to the least significant bit.
- The main advantage of 2's complement is that most operations are not dependent on the sign of the operands and furthermore are identical to operations on unsigned binary integers¹.
- An additional advantage is that if the final sum is within the range; even if partial sums result in overflows the final sum will be correct.

Examples are shown in the next two slides

Mantissa & Exponent

- Numbers are represented using two fixed point numbers a mantissa m , and an exponent e .

Mantissa & Exponent

- Numbers are represented using two fixed point numbers a mantissa m , and an exponent e .

$$\text{Number} = m \cdot 2^e$$

Note it is not essential to use the powers of 2; any powers can be used.

- Numbers are represented using two fixed point numbers a mantissa m , and an exponent e .

$$\text{Number} = m \cdot 2^e$$

Note it is not essential to use the powers of 2; any powers can be used.

- There are many ways to create floating point numbers.

- Numbers are represented using two fixed point numbers a mantissa m , and an exponent e .

$$\text{Number} = m \cdot 2^e$$

Note it is not essential to use the powers of 2; any powers can be used.

- There are many ways to create floating point numbers. One (common) method is keeping the mantissa in the range

$$-1 \leq m < 1$$

; and keeping the exponent as an unsigned binary integer.

- Numbers are represented using two fixed point numbers a mantissa m , and an exponent e .

$$\text{Number} = m \cdot 2^e$$

Note it is not essential to use the powers of 2; any powers can be used.

- There are many ways to create floating point numbers. One (common) method is keeping the mantissa in the range

$$-1 \leq m < 1$$

; and keeping the exponent as an unsigned binary integer.

- The number of bits b must be split into two; some bits for the mantissa and some for the exponent.

- The resolution of fixed point numbers is uniform; however for floating point numbers the resolution varies; the resolution is fine for small numbers and coarse for large numbers.

- The resolution of fixed point numbers is uniform; however for floating point numbers the resolution varies; the resolution is fine for small numbers and coarse for large numbers.
- The greater the number of bits used for the exponent the larger the dynamic range of the numbers, but the lower the accuracy of the numbers.

- The resolution of fixed point numbers is uniform; however for floating point numbers the resolution varies; the resolution is fine for small numbers and coarse for large numbers.
- The greater the number of bits used for the exponent the larger the dynamic range of the numbers, but the lower the accuracy of the numbers.
- Normally around $\frac{3}{4}$ of the bits are used for the mantissa and $\frac{1}{4}$ of the bits are used for the exponent².

- The greater the number of bits used for the exponent the larger the dynamic range of the numbers, but the lower the accuracy of the numbers.
- Normally around $\frac{3}{4}$ of the bits are used for the mantissa and $\frac{1}{4}$ of the bits are used for the exponent².

Floating point representation results in rounding errors for both addition and multiplication whereas in fixed point notation, only multiplication results in rounding errors.

²See the IEEE 754 standard for 32 bit floating point numbers

- In all cases there are only $2^8 = 256$ possible numbers.

- In all cases there are only $2^8 = 256$ possible numbers.
- The 2's Complement number ranged from -1 to almost $+1$;

- In all cases there are only $2^8 = 256$ possible numbers.
- The 2's Complement number ranged from -1 to almost $+1$; whereas the floating point numbers range depends on the number of bits used for the exponent.

- In all cases there are only $2^8 = 256$ possible numbers.
- The 2's Complement number ranged from -1 to almost $+1$; whereas the floating point numbers range depends on the number of bits used for the exponent.

Thus when we implement digital filters we need to know the range of all the numbers. This includes the range of numbers at

1. The filter input
2. The filter output
3. The filter coefficients

Thus when we implement digital filters we need to know the range of all the numbers. This includes the range of numbers at

1. The filter input
2. The filter output
3. The filter coefficients

The addition and multiplication can be done using the instructions of the microprocessor or using new routines (written by the programmer/engineer).

Questions

Finite Precision Effects

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients.

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients. Since these are finite precision, there are differences between the ideal poles and zeros and the actual poles and zeros of the filter.

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients. Since these are finite precision, there are differences between the ideal poles and zeros and the actual poles and zeros of the filter. Poles close to the unit circle are the most sensitive.

Finite Precision Effects

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients. Since these are finite precision, there are differences between the ideal poles and zeros and the actual poles and zeros of the filter. Poles close to the unit circle are the most sensitive.
- The addition and multiplication of finite precision numbers will also lead to rounding of the results.

Finite Precision Effects

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients. Since these are finite precision, there are differences between the ideal poles and zeros and the actual poles and zeros of the filter. Poles close to the unit circle are the most sensitive.
- The addition and multiplication of finite precision numbers will also lead to rounding of the results.
- Also IIR filters (filters with feedback) are more sensitive. The feedback of rounding errors can cause oscillations in computation.

Finite Precision Effects

- The size of the registers where filter coefficients and data stored determines the accuracy with which we can represent filter coefficients. Since these are finite precision, there are differences between the ideal poles and zeros and the actual poles and zeros of the filter. Poles close to the unit circle are the most sensitive.
- The addition and multiplication of finite precision numbers will also lead to rounding of the results.
- Also IIR filters (filters with feedback) are more sensitive. The feedback of rounding errors can cause oscillations in computation. **This effect is known as Limit Cycle.**

The effect of filter finite precision coefficient on the poles (and zeros) of a filter depends on how close the poles are to each other

The effect of filter finite precision coefficient on the poles (and zeros) of a filter depends on how close the poles are to each other

- Poles that are close together are more sensitive to finite precision effects

Thus a strategy for implementing filters is to

The effect of filter finite precision coefficient on the poles (and zeros) of a filter depends on how close the poles are to each other

- Poles that are close together are more sensitive to finite precision effects

Thus a strategy for implementing filters is to

- Cascade many smaller filters which have poles (and zeros) as far apart as possible.

The effect of filter finite precision coefficient on the poles (and zeros) of a filter depends on how close the poles are to each other

- Poles that are close together are more sensitive to finite precision effects

Thus a strategy for implementing filters is to

- Cascade many smaller filters which have poles (and zeros) as far apart as possible.
- Have in parallel many smaller filters with the same criteria above.

In practice the cascade form is used as it is more robust to quantisation effects. Also poles closer to the origin are implemented first.

Typically filters with two or fewer poles are implemented.

If the transfer function has m poles and zeros, with zeros at locations α and poles at locations β ; the transfer function can be written as

$$H(Z) = \frac{(Z - \alpha_0)(Z - \alpha_1) \cdots (Z - \alpha_{m-1})}{(Z - \beta_0)(Z - \beta_1) \cdots (Z - \beta_{m-1})}$$

The design choice for practical implementation is the cascade form

If the transfer function has m poles and zeros, with zeros at locations α and poles at locations β ; the transfer function can be written as

$$H(Z) = \frac{(Z - \alpha_0)(Z - \alpha_1) \cdots (Z - \alpha_{m-1})}{(Z - \beta_0)(Z - \beta_1) \cdots (Z - \beta_{m-1})}$$

The design choice for practical implementation is the cascade form

$$H(Z) = \prod \frac{b_{k0} + b_{k1}Z^{-1} + b_{k2}Z^{-2}}{1 + a_{k1}Z^{-1} + a_{k2}Z^{-2}}$$

If the transfer function has m poles and zeros, with zeros at locations α and poles at locations β ; the transfer function can be written as

$$H(Z) = \frac{(Z - \alpha_0)(Z - \alpha_1) \cdots (Z - \alpha_{m-1})}{(Z - \beta_0)(Z - \beta_1) \cdots (Z - \beta_{m-1})}$$

The design choice for practical implementation is the cascade form

$$H(Z) = \prod \frac{b_{k0} + b_{k1}Z^{-1} + b_{k2}Z^{-2}}{1 + a_{k1}Z^{-1} + a_{k2}Z^{-2}}$$

or the parallel form

If the transfer function has m poles and zeros, with zeros at locations α and poles at locations β ; the transfer function can be written as

$$H(Z) = \frac{(Z - \alpha_0)(Z - \alpha_1) \cdots (Z - \alpha_{m-1})}{(Z - \beta_0)(Z - \beta_1) \cdots (Z - \beta_{m-1})}$$

The design choice for practical implementation is the cascade form

$$H(Z) = \prod \frac{b_{k0} + b_{k1}Z^{-1} + b_{k2}Z^{-2}}{1 + a_{k1}Z^{-1} + a_{k2}Z^{-2}}$$

or the parallel form

$$H(Z) = \sum \frac{c_{k0} + c_{k1}Z^{-1}}{1 + a_{k1}Z^{-1} + a_{k2}Z^{-2}}$$

There are many software tools that can be used to select the best strategy. In practice, MATLAB[®] is normally used. **Remember there is no optimum method that works for all types of filters.**
